Opioids for osteoarthritis pain: benefits and risks

Noah Ivers MD CCFP  Irfan A. Dhalla MD MSc FRCPC  G. Michael Allan MD CCFP

Clinical question
What is the evidence for opioids for osteoarthritis (OA) pain?

Evidence
Benefits: There is no high-quality evidence that opioids improve function more than nonopioid analgesics.1,2
- Systematic review: nontramadol opioids for OA3:
  - 10 RCTs (N=2268) with maximum 12-week treatment.
    - More patients reported 50% improvement in pain than with placebo (NNT=25).
      - Median dose: 51 mg of morphine equivalent per day; higher doses did not increase benefits.
    - Function improved 0.7 points (scale 0 to 10).
- Systematic review: tramadol for OA4:
  - 11 RCTs (N=1939) with maximum 12-week treatment.
    - More patients reported 50% improvement or at least “moderate” improvement than with placebo (NNT=6).
    - Function improved 0.3 points (scale 0 to 10).
- Side effects caused 1 in 8 patients to stop treatment.
- Pain reduction is equivalent for topical and oral NSAIDs in most cases.8
- Opioids and NSAIDs had similar risk of GI bleeding.
- Patients prescribed opioids had a higher risk of fracture compared to those prescribed NSAIDs (estimated NNH=26).
- Opioids increased risk of cardiovascular events, hospitalization, and overall mortality (estimated NNH=17-27).
- Opioids and NSAIDs had similar risk of GI bleeding.
- Opioid risk is likely exaggerated by selection bias and confounding.

Context
- Only small differences are seen between OA treatments and placebo (standard mean difference [95% CI]): acetaminophen 0.13 (0.22 to 0.04),6 NSAIDs 0.23 (0.16 to 0.31),7 and nontramadol opioids 0.36 (0.26 to 0.47).3
- Pain reduction is equivalent for topical and oral NSAIDs in most cases.8
- International OA guidelines recommend strong opioids only in exceptional cases.9
- Opioid risks are dose-dependent: More than 100 mg of morphine equivalent per day (eg, about 20 mg of hydro-morphine or 66 mg of oxycodone) is associated with increased risk of opioid-related mortality.10,11
- Prescription opioids are a common source of opioid misuse.12 Most opioid overdose deaths occur in individuals who are prescribed opioids.13

Bottom line
No research demonstrates long-term improvement in OA pain or function with opioids. In elderly patients, it is unclear if opioids or NSAIDs are safer. Opioids should not be routinely used in OA but if they are necessary, use them with caution and monitor carefully.

Implementation
When patients are in chronic pain, clinicians are obliged to treat (beneficence), but are also obliged to do no further harm (nonmaleficence). The Cochrane Musculoskeletal Group produced a patient decision aid to help health care providers work with patients to balance these goals when treating OA pain.14 Consider having patients evaluated for joint replacement if pain from OA is severe, as surgery improves long-term function.15
